## MERCHANTABLE VOLUME CONVERSION FACTORS AND TAPER EQUATIONS FOR COMMERCIALTREE SPECIES OF ONTARIO

I.S. Alemdag

## INTRODUCTION

The merchantable volume of single trees or stands is widely required in forestry. Many lumber companies, for example, base their operations on the merchantable volume they obtain from the forest. Merchantable volume of a tree can be defined as the volume of a stem from a given stump height to a given merchantable diameter or to a specified height along the stem. For a given utilization standard this volume changes with the size of the stem in both its absolute and relative (percentage) values. This makes it necessary to develop prediction equations for different utilization standards as well as for different tree sizes. Taper curves, volume equations for a given diameter of utilization, and ratio expressions for variable merchantable diameters and merchantable heights are the three main approaches to estimate merchantable volume. Examples of studies using these concepts are by Behre (1927), Bennett et al. (1959), and Burkhart (1977), respectively. Taper equations arealso useful for calculating stem volume, and for estimating the efficiency of sawmilling and lumber production operations.

In an earlier report (Alemdag 1988), the ratio concept was studied in detail. A method for merchantable volumeestimation was developed and taper equations were derived for one softwood species and one hardwood species in Ontario. Using the same method, the aim of the present report is to present merchantable volume con-
version factors for 28 commercial tree species in Ontario. The species studies are listed in Table1.

## DATA

The data employed in this study were collected in 1978-1983 as a part of two biomass studies. A summary is presented in Table 2. All sample trees were cut at a fixed stump height of 0.30 m . In addition to breast height diameter, diameters at three locations along the stem were measured: one where diameter outside bark was 9.2 cm , and the others at $1 / 3$ and $2 / 3$ of the height from ground level to the 9.1 cm point. Heights to these threelocations were alsotaken. Later, the volume of each of these $1 / 3$ sections was calculated.

It should be noted that here, diameters are expressed in centimetres, heights (including stump height) in metres, and volumes in cubic metres (inside bark, regardless of decay and defect).Thus:

$$
\begin{aligned}
\mathrm{D}= & \text { breast height diameter at } 1.30 \mathrm{~m}, \\
& \text { outside bark } \\
\mathrm{d}= & \text { merchantable top diameter, inside } \\
& \text { bark } \\
\mathrm{H}= & \text { total tree height } \\
\mathrm{h}= & \text { merchantable height (height from } \\
& \begin{array}{l}
\text { ground level to a specified utilization }
\end{array} \\
& \text { limit) } \\
\mathrm{hs}= & \text { stump height } \\
\mathrm{VT}= & \text { total stem volume from ground level } \\
& \text { to the tip of the tree } \\
\mathrm{VM}= & \text { merchantable volume (volume from } \\
& \text { stump height to a specified utilization } \\
\mathrm{VS30}= & \text { limit) } \\
\mathrm{VS}= & \text { stump volume at } 0.30 \mathrm{~m} \text { stump height } \\
\mathrm{VP}= & \text { top volume atume a given stump height } \\
& \text { able top diameter, or, above a given } \\
& \text { merchantableheight } \\
\mathrm{VL}= & \text { ground-to-limit volume (volume } \\
& \text { from ground level to a specified } \\
& \text { utilization limit) }
\end{aligned}
$$

Figure 1 illustrates these variables.

Figure 1. Volume components of a stem and its dimensional measurements.

## METHOD

Because the method of developing merchantable volume conversion factors as ratios was explained in detail by Alemdag (1988), only a summary is provided here. When volume distribution is studied in two trees of the same
shape (assumed to be proportionally similar in all dimension) it will be seen that volume ratio remains the same for a given $h / H$ ratio and approximately the same for a given d/D ratio. Figure 2 verifies this theorem, illustrating the distribution of volume ratios over relative diameters and relative heights using data from white spruce.

In order to obtain the merchantable volume/total stem volume ratio, the following procedure is followed sequentially: (1) estimate ground-to-limit volume ratio;(2) estimate stump volume ratio; and, (3) estimate merchantable volume ratio. After the merchantable volume ratio is determined, it is used as a conversion factor with a given total stem volume for calculating the merchantable volume.

## RESULTS

Results of the above procedure are provided below:
(1) The ground-to-limit volume ratios (VL/VT, or K) were expressed as a function of $\mathrm{d} / \mathrm{D}$ or $\mathrm{h} / \mathrm{H}$, where d and he are flexible values. Based on the relationships shown in Figure 2, several mathematical models weretested and the most promising, as shown in Table 3, were used in the subsequent analyses. These are conditioned models, because $K$ is 1 when $d / D$ is zero or $\mathrm{h} / \mathrm{H}$ is 1 . The linear regression technique was

Figure 2. Scatterdiagrams showing the relationships of VL/VT ratios with (a) d/Dratios, and (b) h/H ratios: an example with white spruce.
used to develop the equations and the results of the analyses for each species were evaluated by their fit index (FI) (Alemdag 1986) and the standard error of estimate (SEE\%) values. Models 1 and 3 produced almost identical results and also better results than that of Model 2. Similarly, Models 4 and 6 performed better than Model 5 . For these reasons Model 1 was adopted for the d/D expression and Model 4 for the h/Hexpression.* These models for all species, together with their regression coefficients and statistical data, are presented in Table 4.
(2) Estimating stump volume ratios at the 0.30 m stump height (VS30/VT) as a function of D and H, or VT, was not feasible because of the stump volume ratio's weak and insignificant relationships with thesevalues, possiblybccause of inconsistent butt flare. For this reason the mean values of these ratios were adopted for each species as shown in Table 5. However, as these are averages for the 0.30 m stump height and because stump volume ratio may be required at other stump heights, a conversion factor (p) was developed for this purpose by a geometrical method in which the stump was assumed to be the frustum of a neiloid (Alemdag 1988). This factor for all specios is

$$
\begin{equation*}
\mathrm{p}=3.610 \cdot \mathrm{hs}-0.922 \cdot \mathrm{hs}^{2} \tag{1}
\end{equation*}
$$

and the stump volume ratio at a given stump height for each species is

$$
\begin{equation*}
\mathrm{VS} / \mathrm{VT}=(\mathrm{VS} 30 / \mathrm{VT}) \cdot \mathrm{p} \tag{2}
\end{equation*}
$$

(3) Establishing the merchantable volume ratio (VM/VT) or the merchantable volume conversion factor for a given merchantable top diameter or merchantable height is done simply by taking the difference between the ground-tolimit volume ratio and the stump volume ratio. Hence:

$$
\begin{align*}
& \mathrm{VM} / \mathrm{VT}=\mathrm{VL} / \mathrm{VT}-\mathrm{VS} / \mathrm{VT} \text {, or }  \tag{3}\\
& \mathrm{VM} / \mathrm{VT}=\mathrm{VL} / \mathrm{VT}-(\mathrm{VS} 30 / \mathrm{VT}) \cdot \mathrm{p}  \tag{4}\\
& \mathrm{VM} / \mathrm{VT}=1+\mathrm{b}_{1} \cdot(\mathrm{~d} / \mathrm{D})^{\mathrm{b}_{2}}-\mathrm{VS} 30 / \mathrm{VT} \cdot(3.610 \\
& \left.\cdot \mathrm{hs}-0.922 \cdot \mathrm{hs}^{2}\right)  \tag{5a}\\
& \mathrm{VM} / \mathrm{VT}=1+\mathrm{c}_{1} \cdot(1-\mathrm{h} / \mathrm{HI})^{\mathrm{c}_{2}}-\mathrm{VS} 30 / \mathrm{VT} \cdot(3.610 \\
& \left.\cdot \mathrm{hs}-0.922 \cdot \mathrm{hs}^{2}\right) \tag{5b}
\end{align*}
$$

After developing equations for ground-tolimit volume ratios, their effectiveness was checked using an independent set of data. For each individual tree the difference between the
observed values and the estimated values was calculated. Then for all trees of each species the mean absolute difference (bias) was computed. For the $d / D$ expression the weighted average bias for softwoods is +0.011 and for hardwoods +0.018 ; for the $h / H$ expression these are -0.002 and -0.001 , respectively.

Finally the ratio equations developed here were compared with Honer's equations (Honer 1967, and Honer et al. 1983). Honer's two principal merchantable volume ratio equations for six softwood and three hardwood species were used in the comparisons: one as a function of $(d / D)^{2}$ and the other as a function of $h / H$. Both incorporate a variable stump height. These equations, together with their regression coefficients, were applied to the same independent data set which covers a variety of tree sizes, top diameters, and merchantable heights, and the results are summarized in Table 6. Comparison with the performances of equations presented in this report indicate that mean residuals are negligible using both methods and that there is almost no difference between the two approaches. Another comparison, using all nine species and studying behavior of individual observations revealed that there is no systematic error in either method. They both overestimate or underestimate.

If desired, taper equations can be derived from these merchantable volume ratio cquations for estimates of d and h by equating the two VL/VT equations of each species and then solving ford and for $h$ as outlined by Alemdag (1988). Accuracy will be less at both ends of the stem than in between. When developed, these taper equations will have the following forms:

$$
\begin{equation*}
\mathrm{d}=\mathrm{D} \cdot\left[\frac{\mathrm{c}_{1} \cdot(1-\mathrm{h} / \mathrm{H})^{\mathrm{c}_{2}}}{\mathrm{~b}_{1}}\right]^{1 / \mathrm{b}_{2}} \tag{6}
\end{equation*}
$$

$$
\begin{equation*}
\mathrm{h}=\mathrm{H} \cdot\left[1-\left(\frac{\mathrm{b}_{1} \cdot(\mathrm{~d} / \mathrm{D})^{\mathrm{b}_{2}}}{\mathrm{c}_{1}}\right)^{1 / c_{2}}\right] \tag{7}
\end{equation*}
$$

These equations compare very well with the form-class taper curves developed earlier by the Canadian Forestry Service (Anon. 1930 and 1948) and later formulated by Alemdag (1983). For more precise estimates, the method developed by Nown ham (1988) can be used.

[^0]
## APPLICATION OF THE CONVERSION FACTORS AND THE TAPER EQUATIONS

The application of these merchantable volume conversion factors is straightforward and simple. The following steps should be taken:

1. Decideon the merchantable top diameter (d) or merchantable height ( h );
2. Measure breast height diameter (D) or total tree height $(\mathrm{H})$, and the stump height (hs);
3. Calculate $d / D$ or $h / H$, whichever is appropriate;
4. Use the appropriate formula for the species concerned, with the coefficients given in Table 4, for estimating the VL/VT ratio or K;
5. Calculate VS/VT ratio using average VS30/VT ratio from Table 5, and the p of measured hs;
6. Subtract VS/VT from VL/VT to find merchantable volume ratio (VM/VT) for this particular case (Items 4,5, and 6 can be combined into one as illustrated in Equations 5a and 5b);
7. Multiply this merchantable volume conversion factor by the total stem volume (VT) to arrive at merchantable volume. Note that VT could be eight in metric or imperial measure and could also be expressed as a formula.

An example of this procedure is found in Table 7, using white spruce, once for $\mathrm{d} / \mathrm{D}=0.35$ and once for $h / H=0.60$. In this case, 0.35 means, for instance, $7 \mathrm{~cm} / 20 \mathrm{~cm}, 8 \mathrm{~cm} / 22.9 \mathrm{~cm}, 9$ $\mathrm{cm} / 25.7 \mathrm{~cm}$, and 0.60 means, for instance, 12 $\mathrm{m} / 20 \mathrm{~m}, 16 \mathrm{~m} / 26.67 \mathrm{~m}, 18 \mathrm{~m} / 30 \mathrm{~m}$.

It should be noted that the merchantable equations presented in this report can also be used:
(a) with stand averages;
(b) for studying the volume distribution within a stem at various heights or at various stem diameters; and,
(c) for estimating the volume of a segment of a stem between two given heights or between two given stem diameters.

Using taper equations for estimating d requires the knowledge of $\mathrm{D}, \mathrm{H}$ and h , and for estimating $h$, the knowledge of $\mathrm{D}, \mathrm{H}$ and d. For instance for a white spruce with $D=22.0 \mathrm{~cm}$ and $\mathrm{H}=18.60 \mathrm{~m}$, diameter at 15.00 m above ground
is 7.6 cm , and height along the stem to correspond a diameter of 12.5 cm is 11.06 m .

Although these findings are applicable to conditions similar to those in Ontario for any particular species, a test of their adequacy is recommended beforehand. These formulas can easily be incorporated with the calculation programs of an electronic field data collector.
