## FOREST ECOSYSTEM CLASSIFICATION IN ONTARIO'S CLAY BELT

R.W. Arnup and J.K. Jeglum

**CATEGORY:** Forest ecology

**KEY WORDS:** Black spruce, lowland, peatland, forest ecosystem classification

### INTRODUCTION

The Clay Belt forest ecosystem classification project was a cooperative research and development study involving government and educational agencies. Its objectives were to: (i) develop an ecological classification of forest ecosystems with an emphasis on the commercial forest; (ii) provide an initial interpretation and evaluation of the ecosystem types for forest management purposes; and (iii) develop practical aids for identifying, recognizing, and mapping the ecosystem types both on the ground and on aerial photographs.

A field guide to forest ecosystem classification for the Clay Belt was published in 1983 (Jones et al. 1983). The guide described 23 vegetation types and 14 soil types for the Clay Belt. The soil and vegetation types were further integrated, with due consideration of practical operational constraints, to form 14 management-level classes suitable for developing silvicultural prescriptions. These 14 classes were termed operational groups (OGs) and were defined as landscape segments supporting mature forest, which have a known range of soil and vegetation features and probable responses to specific silvicultural prescriptions (Fig. 1).

Depending on the nature of the work, any or all of these basic classification units can be used for site description. For example, field staff doing pre-cut inspections for the purpose of determining management alternatives might use the OGs; forest researchers might use the vegetation and soil types in their work.

### MANAGEMENT CONSIDERATIONS FOR THE BLACK SPRUCE DOMINATED OPERATIONAL GROUPS AND VEGETATION TYPES

Because of the importance of the species, considerable emphasis is placed on the management of black spruce ecosystems in the Clay Belt. Integration of harvesting with regeneration planning and prescriptions is generally viewed as essential for successful management of black spruce ecosystems, since the harvest systems used determine to a great extent the regeneration alternatives available after logging.

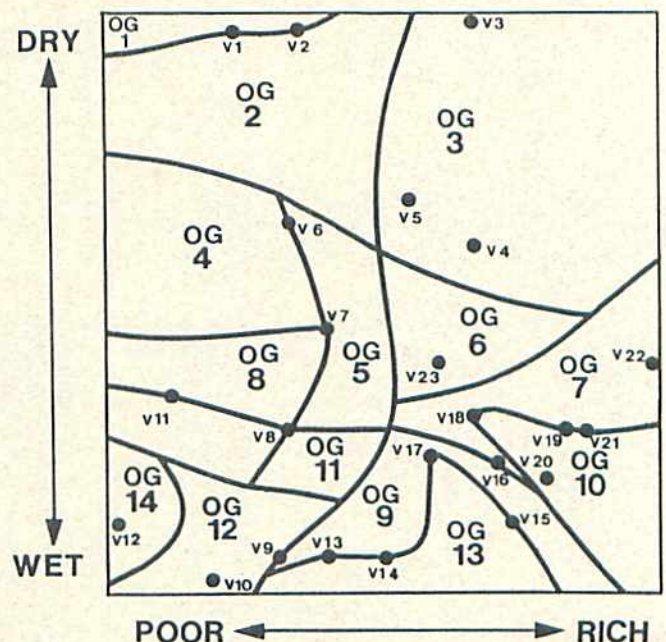

Figure 1. The operational groups included in the Forest Ecosystem Classification for northeastern Ontario.

Canada

There are a number of operational considerations that determine the silvicultural alternatives available for management of a particular black spruce ecosystem. These include trafficability for equipment operations, availability of seedbeds for seed-dependent regeneration prescriptions, site fertility, abundance and distribution of black spruce advance growth for natural regeneration, and availability of food species and shelter for wildlife.

In turn, certain ecosystem elements that are inherent in the Clay Belt FEC system can be used to evaluate the potential suitability and limitations of a site for a particular prescription. Key elements include organic matter depth, humus form, soil texture, moisture regime, forest floor substrates, stand compo-

sition, and understorey plant species. Tables 1 and 2 summarize data for several key ecosystem elements of the black spruce dominated OGs and vegetation types, respectively.

## USE OF THE FEC SYSTEM BY CLAY BELT FOREST MANAGERS

The Clay Belt FEC system has been incorporated into the silvicultural ground rules in most timber management plans in Ontario's Clay Belt. These rules describe the most commonly used management prescriptions by site type. In the ground rules, the OG descriptions serve as a framework for silvicultural prescriptions and help to integrate existing land resource information, including forest resource inventory

**Table 1.** Summary of key ecosystem elements for the black spruce dominated operational groups.

(FRI) working groups, stand types, and soil inventories. Table 3 lists examples of a number of management considerations for the OGs.

## RELATED BLACK SPRUCE RESEARCH

Research conducted under the Canadian Forest Service – Ontario's Black Spruce Ecosystem Program revealed relationships between the abundance and distribution of black spruce advance growth, and the FEC OGs and vegetation types (Groot 1984). Related research showed differences among the FEC OGs with regard to the effectiveness of different harvest methods in protecting advance growth and the site (Groot 1987). Research on black spruce direct seeding can also be related to the FEC by comparing seedbed distribution in the different OGs to determine the probability of success and the seeding rates needed.

**Table 3.** Summary of management considerations for the black spruce dominated FEC operational groups.

| OG No. | Frost-free ground strength class | Suitability for careful logging to protect advance growth | Suitability for direct seeding black spruce | Moose habitat potential, early winter | Moose habitat potential, late winter |
|--------|----------------------------------|---|---|---------------------------------------|--------------------------------------|
| 1      | very good                        | low   | low   | low                                   | low                                  |
| 4      | moderate                         | medium  | low   | low                                   | medium                               |
| 5      | moderate                         | medium  | low   | low                                   | high                                 |

| 14     | very poor                        | unmerchantable  | unmerchantable                              | low                                   | low                                  |

**Table 4.** Productivity rankings for the black spruce dominated operational groups based on different measurement techniques.

| Measurement criterion  | Productivity rankings by OG |         |    |        |    |        |    |
|--|-----------------------------|---------|----|--------|----|--------|----|
|  |                             | Highest |    | -----> |    | Lowest |    |
| Mean annual increment of black spruce stands at age 90 (Ray 1985)    | 5                           | --      | 13 | 12     | 8  | 11     | 14 |
| Black spruce site index at age 100 years (Ray 1985)                  | --                          | --      | 12 | 13     | 8  | 11     | 14 |
| Black spruce 1-year seedling growth (Munson and Timmer 1986)         | 5                           | --      | -- | 12     | -- | 11     | -- |
| Black spruce mean unit needle nitrogen content (Timmer and Ray 1988) | 5                           | 4       | 8  | 13     | 12 | 11     | 14 |
| Black spruce site index at age 100 years (Whynot and Penner 1990)    | --                          | 8       | 13 | 5      | 12 | 11     | 14 |
| Black spruce foliar nitrogen content (Nieppola et al. 1993)          | 5                           | 4       | 12 | 13     | 8  | 11     | 14 |

Although the Clay Belt classification was not intended to address timber productivity, there has been considerable interest in this topic. A number of studies related to growth and yield have been conducted. Although these studies used different measurement criteria to evaluate productivity, the rankings for the OGs have proved to be similar (Table 4). This suggests that the Clay Belt site classification provides a reasonable approximation of timber productivity classes.

## MANAGEMENT APPLICATIONS

The Forest Ecosystem Classification system for the Clay Belt was designed to address specific concerns of government and industry forest managers. Since the *Clay Belt Forest Ecosystem Classification Field Guide* was published, solutions to many of these problems have been found. The FEC has played an important role in this process by provid-

ing a useful framework for inventory, research, management interpretations, and prescriptions. Perhaps the most valuable contribution of the FEC system has been in providing a common framework for communication—a "site language", and today forest managers in the Clay Belt are "talking FEC".

The principal applications of the Clay Belt FEC classification are as follows:

1. It provides a practical system for site recognition in the field that is easy to teach, learn, and use. It takes 1 or 2 minutes to allocate a field site to an operational group.
2. It is reliable and repeatable since it is based on a substantial data base and a comprehensive analysis.
3. It provides a meaningful framework to organize and build upon our present and future forest management experience. Since the system is applicable over the entire Clay Belt, management experience gained in other areas can be compared and transferred. For example, it can help in deciding the season and method of harvesting, potential for black spruce advance growth, regeneration method (natural, seeding, planting), and vegetation management options.
4. It provides consistency: through a common naming system for inventory, management interpretations, and planning and a framework for integrating and interpreting existing land resource inventories, such as the FRI and soils maps.

5. It provides a common system for site description, a framework for field-oriented research and development work, and facilitates transfer of research knowledge.

6. Habitat-potential maps are used to determine the applicability of timber management guidelines for the provision of moose habitat. (Ontario Ministry of Natural Resources 1986). It provides a "site language" to permit communication among foresters, biologists, field technicians, equipment operators, planners, and researchers; in fact, anyone involved in forestry work.

Rob Arnup

John Jeglum

Rob Arnup is a principal in the firm Ecological Services for Planning Ltd. in Timmins, Ontario. He is a forest ecologist with extensive experience in forest management techniques and site classification in the boreal forest of Ontario. He prepared this technical note under contract.

Dr. John Jeglum is a research scientist with the Canadian Forest Service—Ontario. He conducts research in natural regeneration of black spruce, vegetational succession, wetland ecology and classification, and wetland forestry and drainage.

The preparation of this note was funded under the Northern Ontario Development Agreement's Northern Forestry Program.
